Masquera

Collect, animate, and battle with NFT werewolf characters in a Web3 social deduction game

The Problem & Our Solution

Most Web3 games treat NFTs as static speculative art. Masquera turns NFT werewolf characters into functional, trait-driven game pieces.

- NFT games often ignore art and identity, reducing collectibles to flippable JPEGs
- Players want characters with real gameplay utility, not just rarity rankings
- Masquera gives each NFT a trait-based special ability inside werewolf matches
- Anime-style animated art builds emotional attachment that static art cannot
- Trait metadata directly powers gameplay, making collecting meaningful again

How It Works

Players mint, equip, and play animated NFT werewolf characters whose on-chain traits determine their powers during live matches.

- Player mints an animated NFT werewolf with randomized trait-based role (Seer, Witch, etc.)
- Player joins a match; their character's traits are read from on-chain metadata
- Smart contract resolves abilities on-chain: reveals, double-votes, immunity, and more
- Built with Anchor and Rust on Solana, using Metaplex Token Metadata for traits
- Marketplace lets players trade or rent characters between matches via wallet adapter

Built with

Solana, Anchor, Metaplex Token Metadata, Rust, React, Figma/Procreate pipeline for animation export, Solana Wallet Adapter

Why Now & What's Next

Mature Solana NFT tooling and demand for utility-driven NFTs make this the right moment to merge collectible art with real gameplay.

- Metaplex's tooling now makes trait-driven on-chain ability logic practical to ship
- Market demand is shifting from speculative NFTs toward usable, playable assets
- Next: themed NFT character drops with partner artists for new role types
- Next: character leveling and evolution mechanics tied to match win history
- Next: cross-game character portability through an open metadata standard
